LOIKKA

Non-destructive tests

- Temperature history and size of concrete elements differ from laboratory samples → change in early compressive strength (f_{ck})

Rebound number

Ultrasound pulse velocity

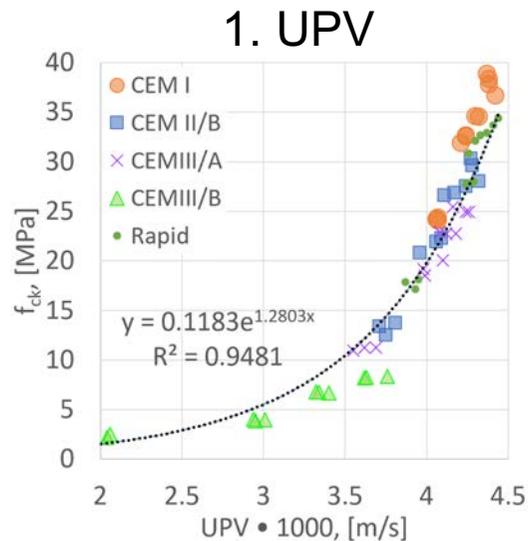

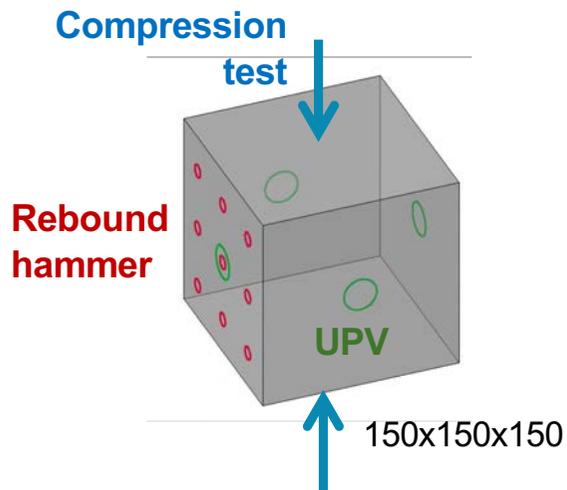

Temperature evolution
Continuous

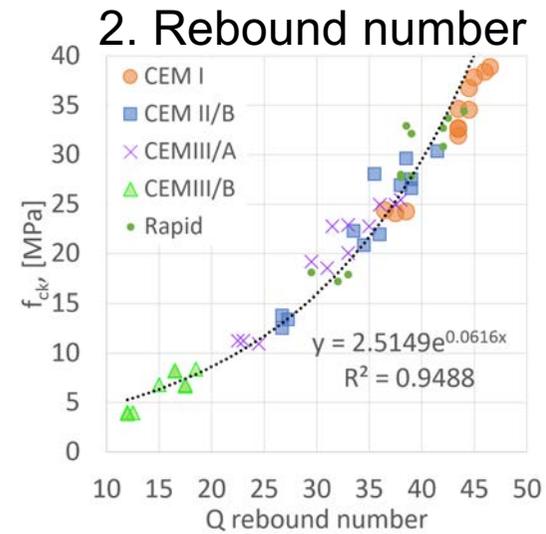

16, 24, 39, 48 hours

Find relationship:

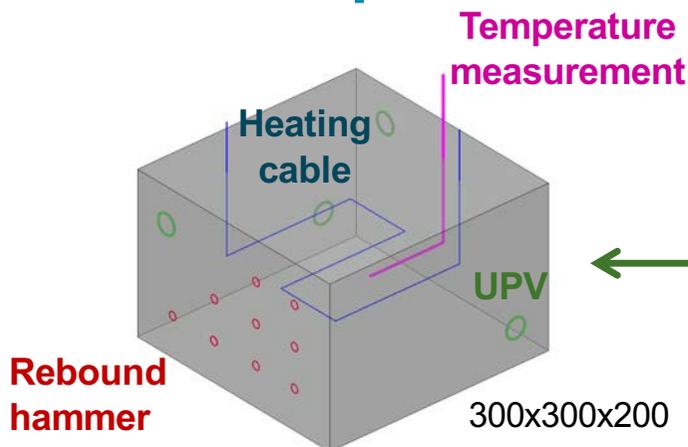

f_{ck} vs. UPV/rebound hammer

Error: 6.6%

Error: 4.9%

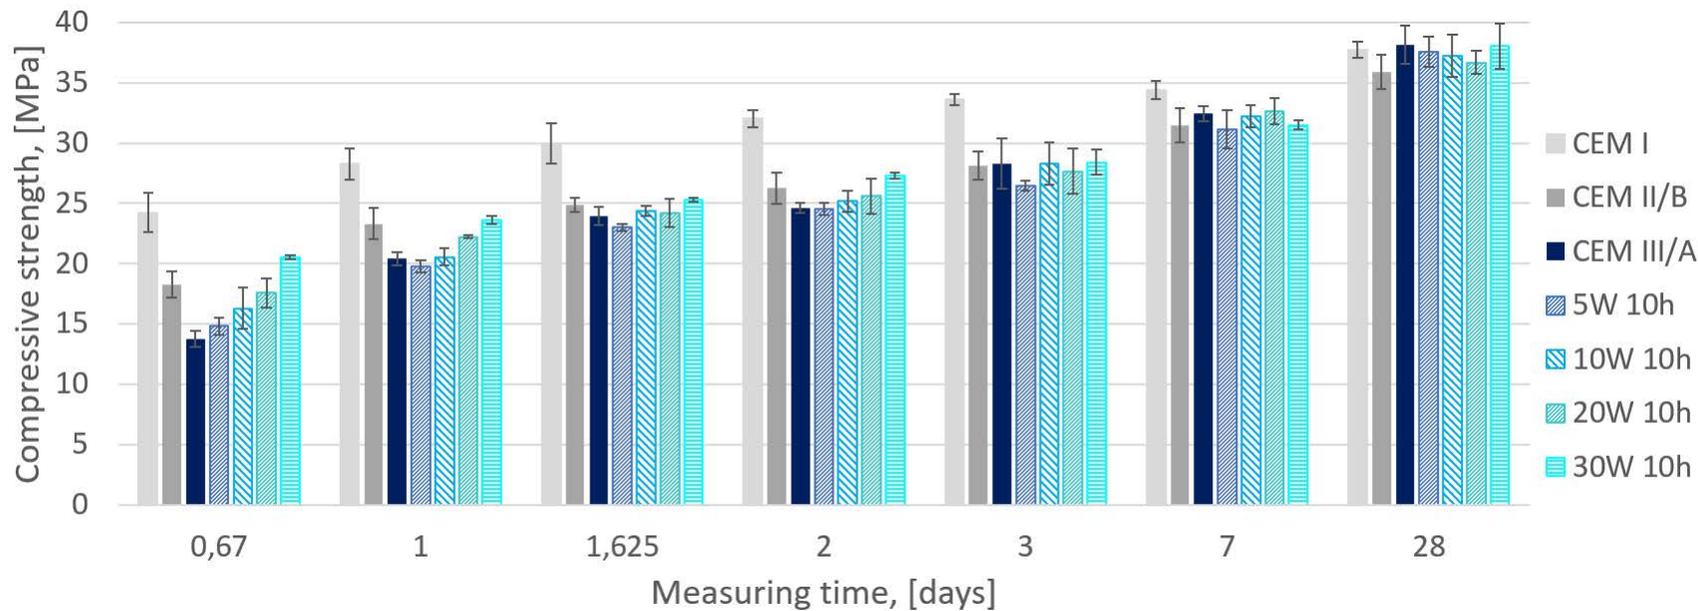

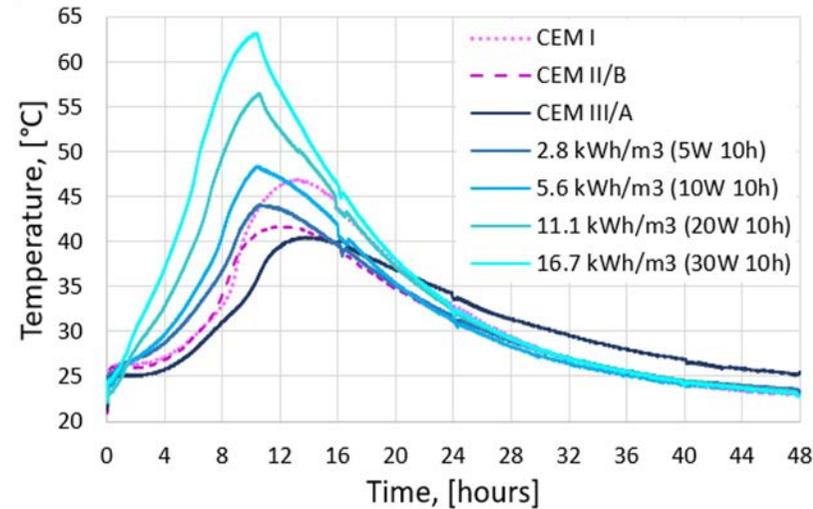

3. SonReb: UPV + RN

$$f_c = 2,33 \times 10^{-9} \times UPV^{2,32} \times RN^{1,04}$$

Error: 3.5%

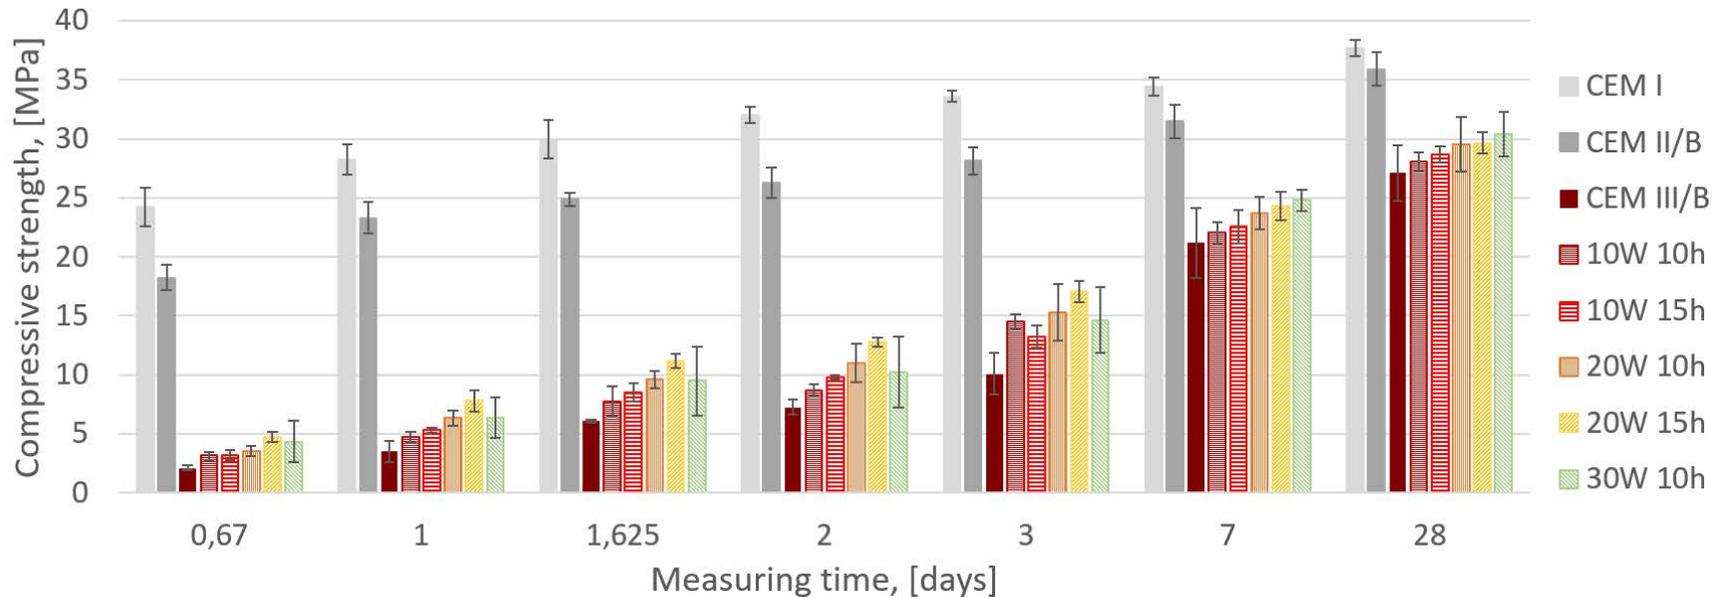

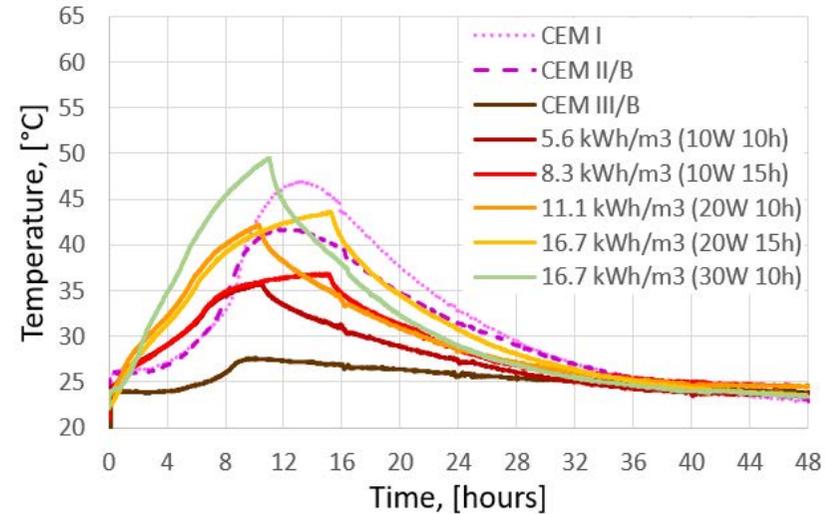

CEM III/A (~40% of slag)

With heat curing of 16.7 kWh/m³ CEM III/A reaches and exceeds f_{ck} of CEM II/B

CEM III/B (~70% of slag)

Heat curing was not sufficient to accelerate f_{ck} of CEM III/B

Chemical activation

LOIKKA

Commercial activators

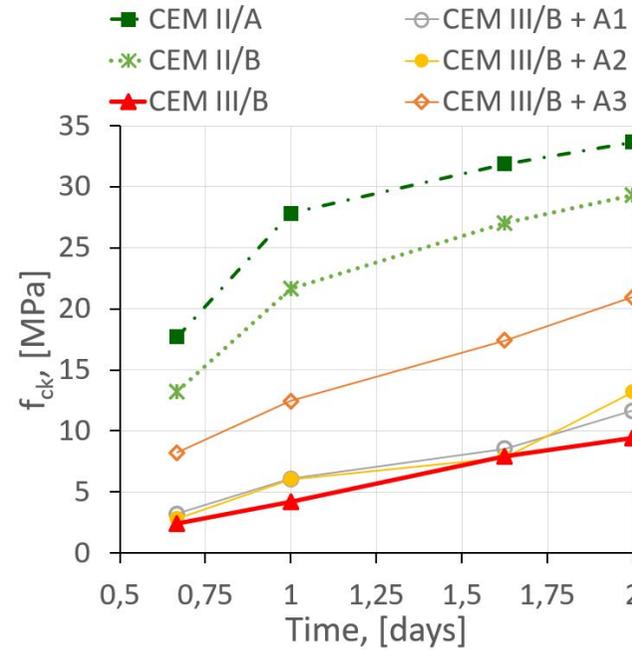

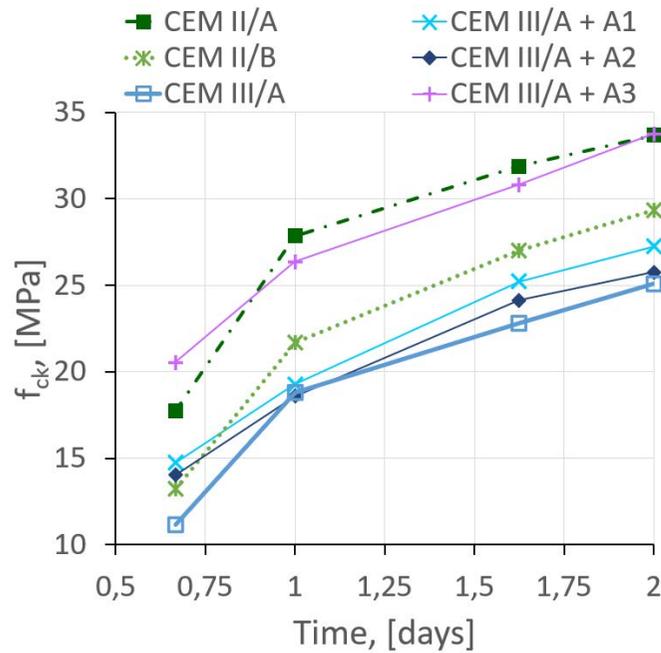

Early strength development

CEM III/A (42% of slag)
CEM III/B (70% of slag)

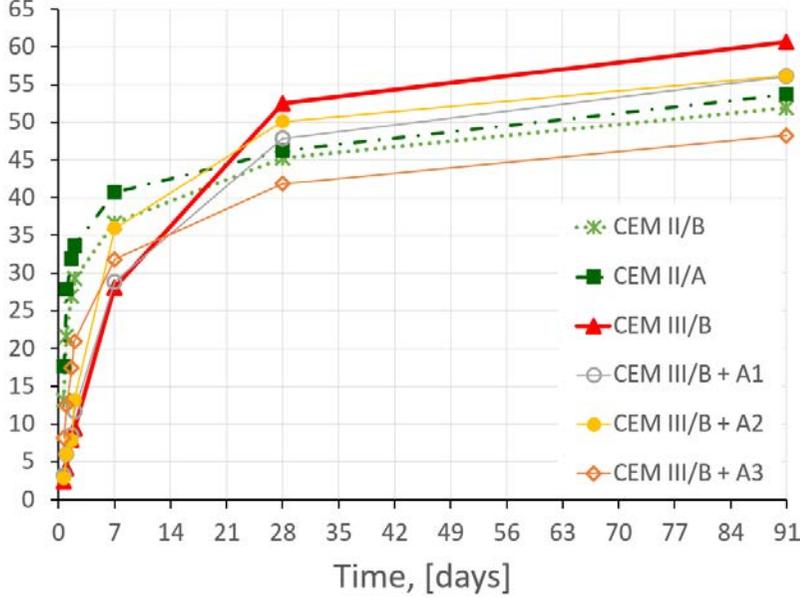

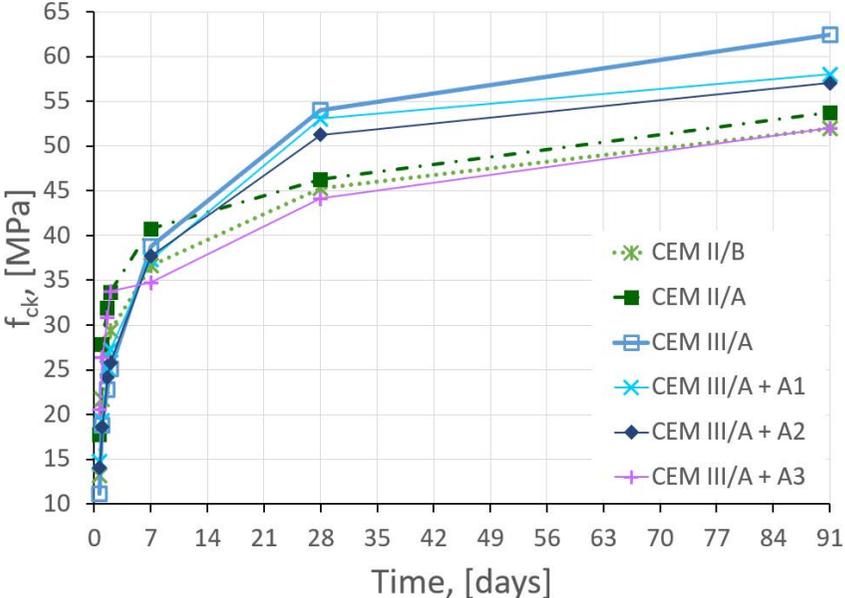

A1 – x-seed
A2 – Calcite-based
A3 – Alkali-based

Commercial activators

Compressive strength at later ages

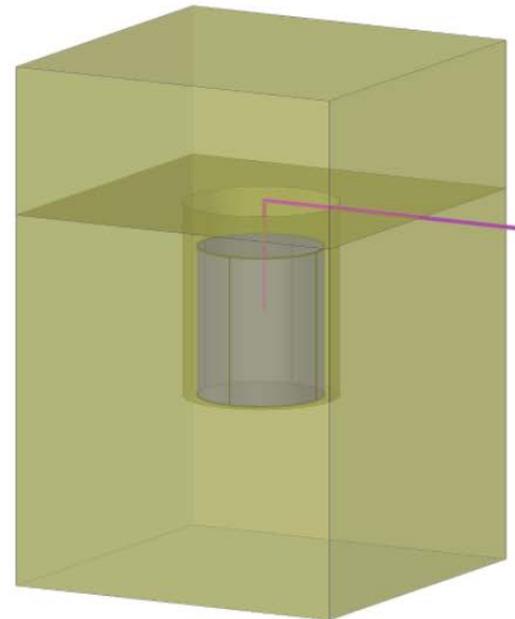

Alkali-activators

Prisms

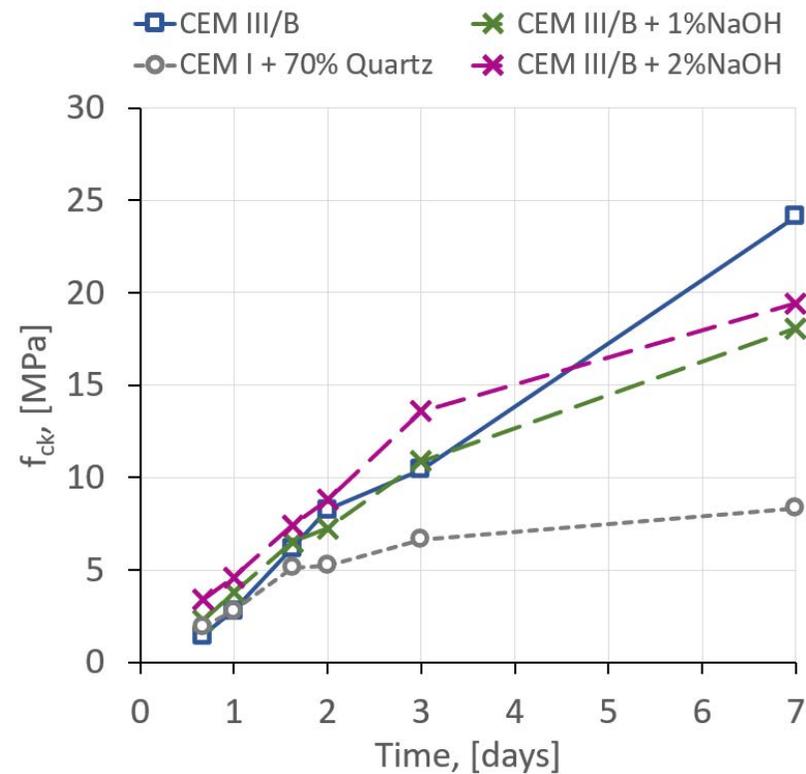

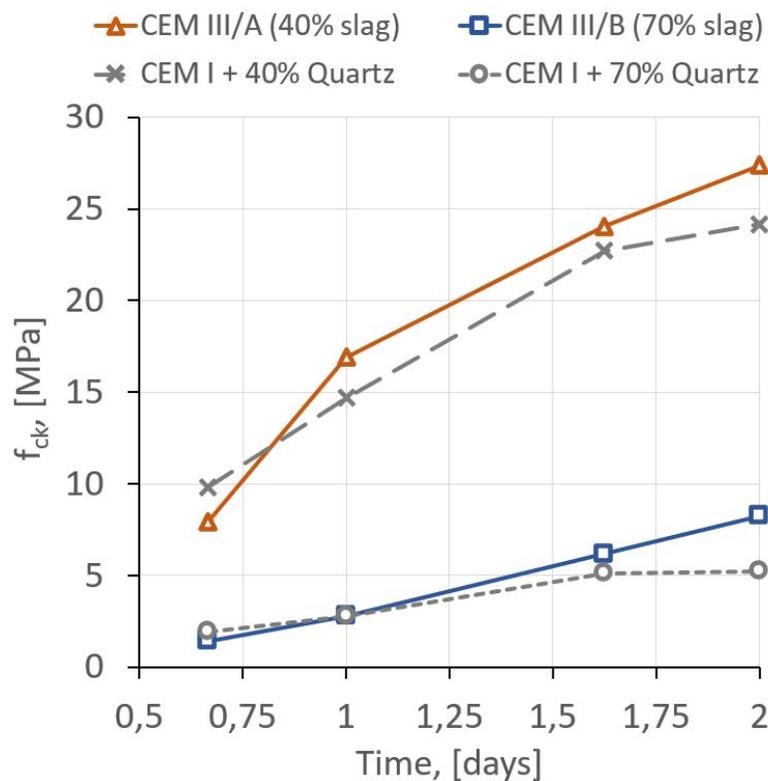

40×40×160

Insulated box

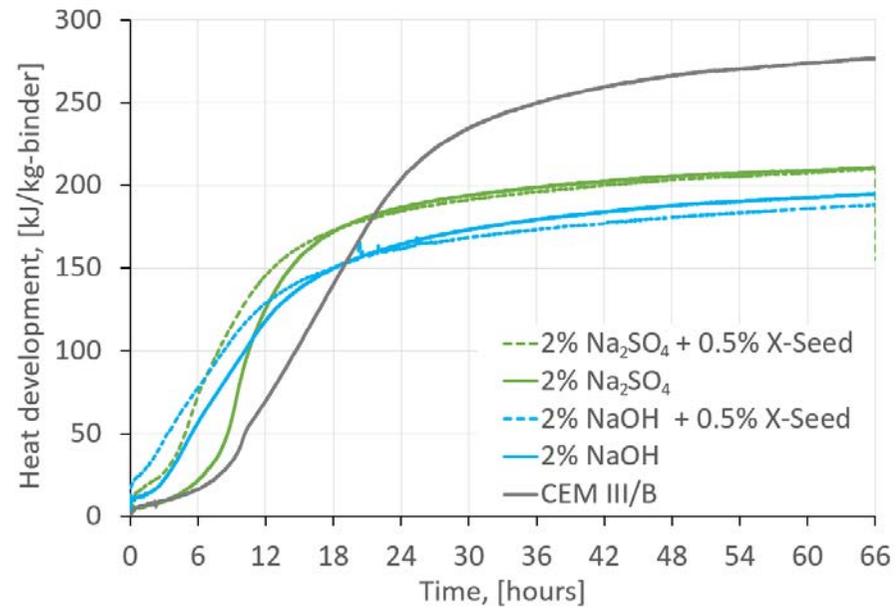

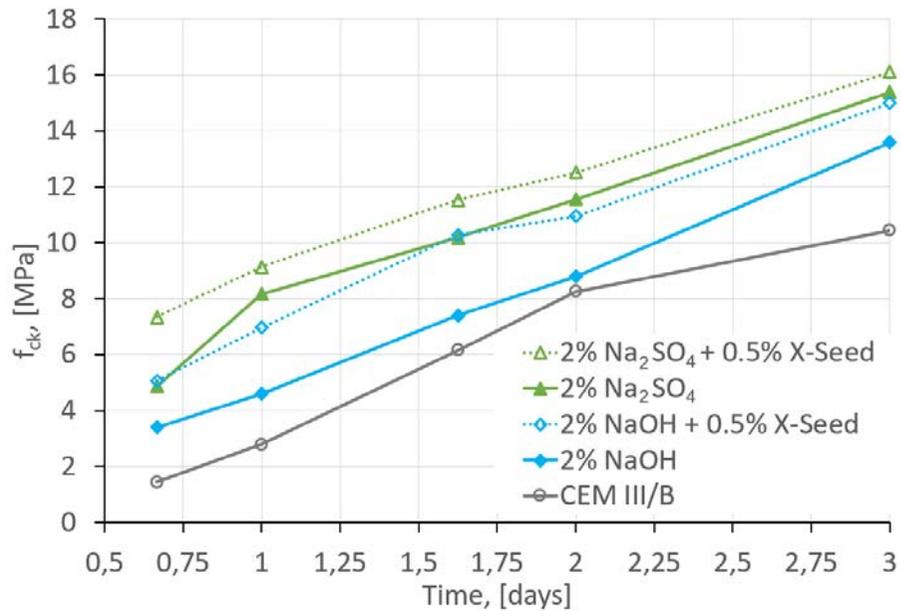

Slag reactivity with and without chemical activation

Alkali-activators

CEM III/B + NaOH/Na₂SO₄ + X-Seed

Summary

1. CEM III/A (40% slag):

- Easy to accelerate compressive strength with both thermal and chemical activation.

2. CEM III/B (70% slag):

- Thermal activation was not efficient
- Chemical activation to be considered as the main solution
→ requires further research
